Sales Prediction using Regression Models in Big Data Analytics

A Project-Based Report in Big Data Analytics (23DSB3303R) Submitted in partial fulfillment of the requirements for the award of the degree of

BACHELOR OF TECHNOLOGY

In

Computer Science and Engineering

By

Vaishnavi Ponnuru - 2320030005

B. Bhavika Sree - 2320030029

V. Charita Sree - 2320030143

Under the Guidance of

Dr. Venkateswara Rao K
Associate Professor

DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

KONERU LAKSHMAIAH EDUCATION FOUNDATION
(DEEMED TO BE UNIVERSITY)

BOWRAMPET, HYDERABAD-500043, TELANGANA, INDIA.

MARCH - 2026

DECLARATION

The Project-Based Report in **Big Data Analytics (23DSB3303R)** entitled "**Sales Prediction using Regression Models in Big Data Analytics"** is a record of Bonafide work of **Vaishnavi Ponnuru (2320030005), B. Bhavika Sree (2320030029), V. Charita Sree (2320030143),** submitted in partial fulfillment of the requirements for the award of B. Tech in Computer Science and Engineering to the Koneru Lakshmaiah Education Foundation. The results embodied in this report have not been copied from any other Department/University/Institute.

Vaishnavi Ponnuru (2320030005)

B. Bhavika Sree (2320030029)

V. Charita Sree (2320030143)

CERTIFICATE

This is to certify that the project-based report **Big Data Analytics (23DSB3303R)** entitled **"Sales Prediction using Regression Models in Big Data Analytics"** is Bonafide work done and submitted by **Vaishnavi Ponnuru (2320030005), B. Bhavika Sree (2320030029), V. Charita Sree (2320030143),** in partial fulfillment of the requirements for the award of the degree of BACHELOR OF TECHNOLOGY in the Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation, during the academic year 2025–2026.

Guide	HOD
Dr. Venkateswara Rao K	**Dr. Venkateswara Rao P**
Associate Professor	**Associate Professor**
Dept. of CSE	**Dept. of CSE**

ACKNOWLEDGEMENT

With great pleasure, we want to take this opportunity to express our heartfelt gratitude to all the people who helped in making this project a grand success.

We are grateful to **Dr. Venkateswara Rao K,** Associate Professor Department of Computer Science and Engineering, for his valuable technical suggestions and guidance during the execution of this project work.

We want to thank **Dr. Venkateswara Rao Pulipati,** Associate Professor**,** Head of the Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation, who is the primary driving force behind completing my project work successfully.

We are very grateful to **Raghavendra G S,** Coordinator-Academics, **Koneru Lakshmaiah Education Foundation**, for his constant support and motivation in successfully carrying out the project work.

We are highly indebted to **Dr. Koteswara Rao L,** Principal, **Koneru Lakshmaiah Education Foundation**, for permitting us to carry out this project in a successful and fruitful way.

We want to thank the **Teaching & Non- teaching** staff of the Department of Computer Science and Engineering for their cooperation.

Finally, we thank our parents, who have stood behind us at different project stages. We sincerely acknowledge and thank those who directly and indirectly support completing this project.

Vaishnavi Ponnuru-2320030005

B. Bhavika Sree-2320030029

V. Charita Sree-2320030143

ABSTRACT

In the contemporary retail environment, accurate sales forecasting is essential for strategic planning, inventory management, and financial decision-making. With the rapid growth of transactional and economic data, traditional forecasting methods often fail to handle large-scale datasets efficiently. This project, titled **"Sales Prediction using Regression Models in Big Data Analytics"**, focuses on developing a regression-based predictive framework using the Walmart sales dataset. The dataset includes historical weekly sales records along with influencing factors such as temperature, fuel price, Consumer Price Index (CPI), unemployment rate, and holiday indicators. The project follows the structured Big Data Analytics lifecycle, including data preprocessing, exploratory data analysis, model planning, model development, and performance evaluation.

Simple Linear Regression and Multiple Linear Regression models were implemented to analyse the relationship between weekly sales and influencing variables. The models were evaluated using statistical metrics such as R-squared, Mean Squared Error (MSE), and Root Mean Squared Error (RMSE). The results indicate that Multiple Linear Regression provides improved predictive performance compared to Simple Linear Regression, although the overall explanatory power remains limited, suggesting that retail sales are influenced by additional complex factors. The study demonstrates the practical application of regression techniques in a Big Data Analytics framework and highlights the importance of data-driven decision-making in modern retail systems.

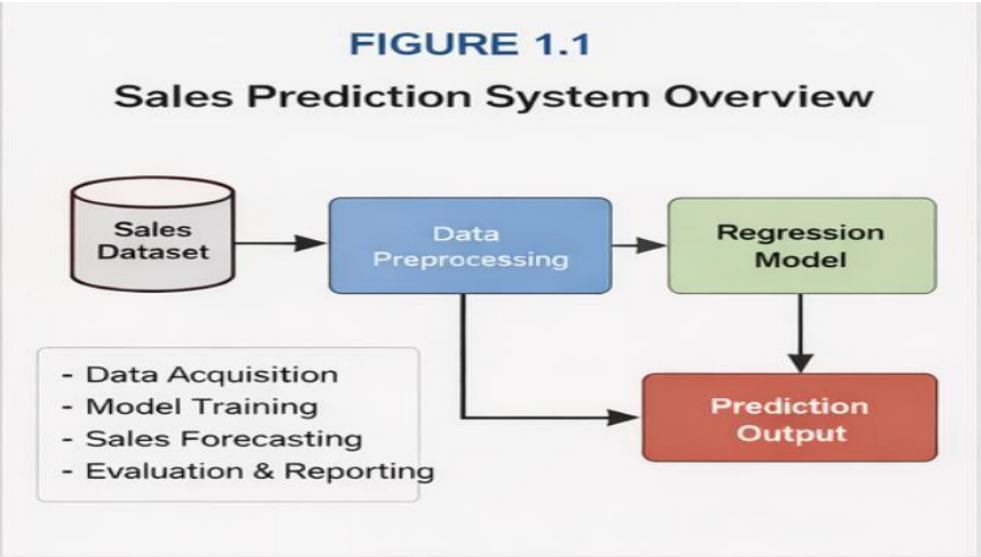
CHAPTER 1
INTRODUCTION

1.1. Problem Statement

Retail organizations generate massive volumes of transactional and economic data. However, traditional analytical approaches are often inadequate for extracting meaningful insights from such large datasets. The primary challenges include:

• Managing high-volume structured data
• Identifying key influencing factors
• Developing interpretable predictive models
• Ensuring statistical validation of results

This project aims to address these challenges by implementing regression-based predictive models within a Big Data Analytics framework



1.2. Research Objective

The Research objectives of this project are:

• To develop regression-based sales forecasting models
• To apply the Big Data Analytics lifecycle systematically
• To analyse the Walmart sales dataset and identify influencing factors
• To evaluate model performance using statistical metrics
• To provide business insights through predictive modelling

1.3 Project Scope and Limitations

Project Scope

- The project aims to predict sales using regression models.
- Historical sales data is analyzed to identify trends and patterns.
- Data preprocessing and basic analysis are performed.
- Multiple Linear Regression is used for sales prediction.
- The system provides predicted sales and basic visualizations.
- Performance metrics are used to evaluate the model.

Limitations

- Accuracy depends on the quality of historical data.
- The model assumes a linear relationship between variables.
- Sudden market or economic changes are not considered.
- Real-time data processing is not included.
- Only regression techniques are used.

CHAPTER 2
BACKGROUND WORK

2.1 Time Series Forecasting using Moving Averages

2.1.1 Introduction

Time series forecasting using Moving Averages is one of the earliest and simplest techniques used for sales prediction. This method predicts future sales by calculating the average of sales values over a fixed historical window. Variants such as Simple Moving Average (SMA) and Exponential Moving Average (EMA) are widely used in traditional forecasting systems.

The moving average technique smooths short-term fluctuations and highlights long-term trends in sales data. Due to its simplicity, it has been extensively used in small-scale retail and inventory management systems.

2.1.2 Merits, Demerits, and Challenges

Merits:

- Simple to understand and implement
- Requires minimal computational resources
- Effective for short-term trend analysis

Demerits:

- Cannot handle multiple influencing factors
- Ignores external variables such as economic conditions
- Poor performance with sudden demand changes

Challenges:

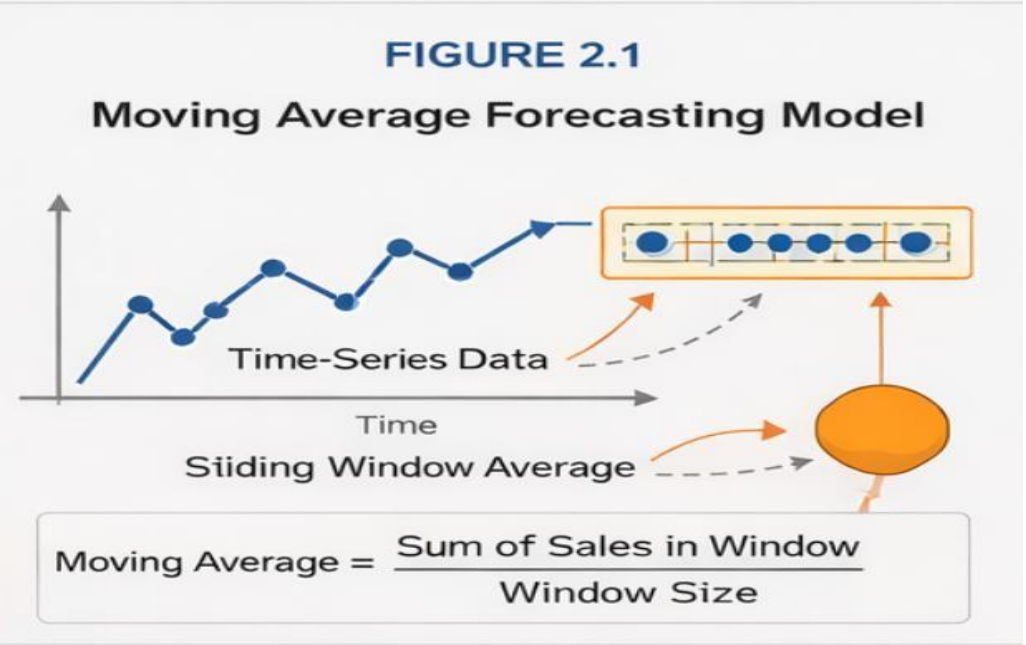
- Not suitable for large-scale datasets
- Limited accuracy in dynamic business environments
- Inadequate for big data analytics applications

2.1.3 Implementation of Moving Average Method

The implementation involves:

1. Selecting a window size (e.g., 3-week or 5-week average)
2. Calculating the average of historical sales within the window
3. Using the computed average as the forecasted sales value

This method relies solely on past sales values and does not include additional explanatory variables.



2.2 ARIMA (AutoRegressive Integrated Moving Average) Model

2.2.1 Introduction

ARIMA is a statistical time-series forecasting model that combines autoregression, differencing, and moving average components. It is widely used for modeling temporal dependencies in sales data and works well when sales patterns show seasonality and trends.

ARIMA models predict future values based on linear combinations of past observations and errors, making them more advanced than basic moving average techniques.

2.2.2 Merits, Demerits, and Challenges

Merits:

- Handles trends and seasonality effectively
- Provides statistically sound forecasts
- Suitable for medium-sized datasets

Demerits:

- Requires stationary data
- Complex parameter tuning
- Cannot easily incorporate multiple external variables

Challenges:

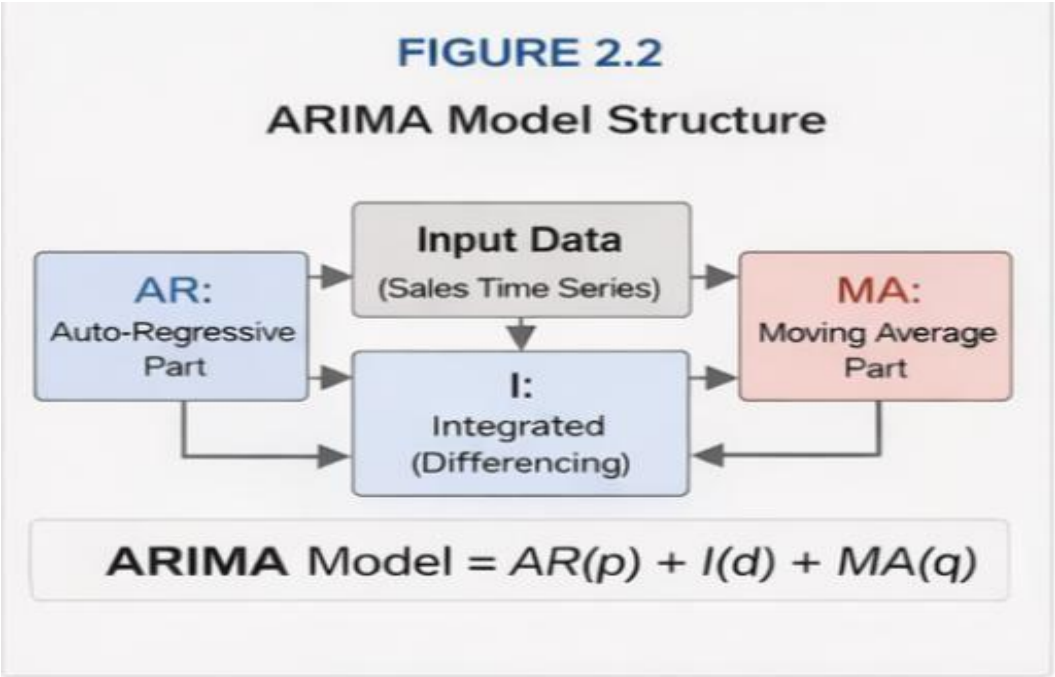
- Difficult to scale for big data environments
- High computational complexity
- Limited interpretability for business user

2.2.3 Implementation of ARIMA Model

The implementation steps include:

1. Making the sales data stationary using differencing
2. Identifying ARIMA parameters (p, d, q)
3. Training the model on historical sales data
4. Generating future sales forecasts

ARIMA improves accuracy over simple methods, but it lacks flexibility when handling large and diverse datasets.



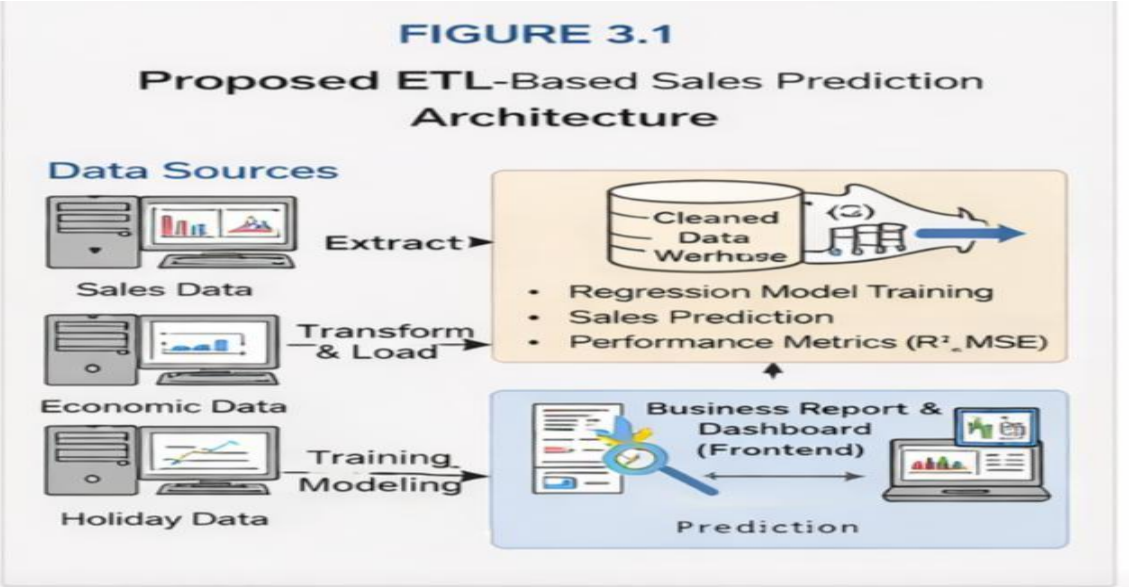
Comparison of Moving Average and ARIMA Models

Parameter	Moving Average Model	ARIMA Model
Model Type	Basic statistical forecasting method	Advanced time-series forecasting model
Ability to Handle Trend	Limited capability	Effectively handles trends through differencing
Ability to Handle Seasonality	Does not handle seasonality	Can handle seasonality
Support for External Variables	Not supported	Limited support through extensions
Model Complexity	Low and easy to implement	High and requires parameter tuning
Computational Cost	Low	Moderate to high
Suitability for Big Data	Not suitable for large-scale datasets	Limited suitability for big data
Prediction Accuracy	Moderate accuracy	Higher accuracy compared to Moving Average

CHAPTER 3
PROPOSED SYSTEM

3.1 Introduction

The proposed system is designed to predict sales using regression models on large-scale retail datasets, similar to Walmart sales data. The framework follows a Big Data Analytics pipeline with ETL (Extract, Transform, Load) processes and regression-based predictive modeling. The goal is to provide accurate sales forecasts that help businesses in inventory management, revenue optimization, and strategic planning.



Dataset Description and Feature Variables

Variable Name	Description	Data Type	Role in Sales Prediction
Store	Unique identification number for each retail store	Categorical	Helps capture store-level differences in sales performance
Date	Week or date of recorded sales	Date	Used to identify trends, seasonality, and time-based patterns
Weekly_Sales	Total sales recorded for a store in a given week	Numeric	Dependent variable (Target) to be predicted
Holiday_Flag	Indicates whether the week contains a major holiday (1 = Holiday, 0 = Non-holiday)	Binary (Categorical)	Captures the impact of holidays on sales volume
Temperature	Average temperature during the week	Numeric	Helps analyze weather influence on customer purchasing behavior
Fuel_Price	Cost of fuel during the week	Numeric	Represents economic conditions affecting consumer spending
CPI	Consumer Price Index	Numeric	Measures inflation impact on sales
Unemployment	Unemployment rate during the week	Numeric	Indicates overall economic health affecting demand

3.2 System Architecture

The proposed system includes the following components:

Data Extraction (E)

- Collect historical sales data from sources such as CSV files, databases, or APIs.
- Include additional relevant data like promotions, holidays, store locations, and product categories.

Data Transformation (T)

- Clean, normalize, and preprocess the data using R (handling missing values, outliers, and categorical encoding).
- Feature engineering to create variables like weekly trends, seasonal indices, and lag variables.

Data Loading (L)

- Store the transformed data in a structured format (e.g., R data frames or SQL databases) for analysis.
- Ensure scalability for large datasets using R with packages like data.table or integration with distributed systems.

Analytics & Regression Modeling

- Implement linear regression, multiple regression, or polynomial regression to forecast sales.
- Evaluate model performance using metrics like RMSE (Root Mean Square Error) or R^2.

Visualization & Reporting

- Create dashboards and charts in R using ggplot2 or Shiny to present predicted vs. actual sales trends.
- Generate actionable insights for decision-makers.

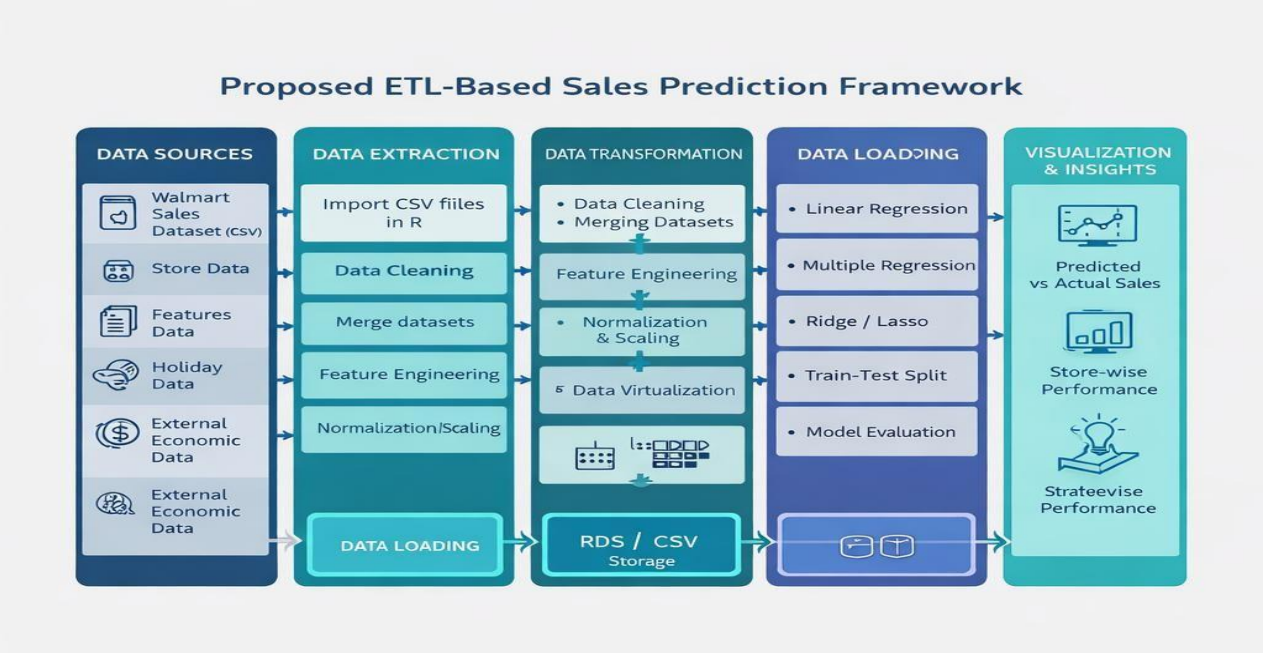
3.3 Features of the Proposed System

- **Scalable ETL Pipeline:** Handles large Walmart-like datasets efficiently.
- **Predictive Accuracy:** Uses regression models tailored to retail data.
- **User-Friendly Visualization:** Dashboards for interpreting trends.
- **Data-Driven Decisions:** Supports inventory planning, promotions, and demand forecasting.

3.4 Workflow

1. Extract historical sales data.
2. Transform and clean data for accuracy.
3. Load the data into structured storage for modeling.
4. Apply regression models to predict future sales.
5. Visualize predictions and trends for business insights.

Proposed ETL-Based Sales Prediction Framework



CHAPTER 4

IMPLEMENTATION

4.1 Code:

```r
sales_data <- read.csv(file.choose())
sales_data <- read.csv("Walmart Dataset.csv")
head(sales_data)
str(sales_data)
summary(sales_data)
```

```
> head(sales_data)
  Store       Date Weekly_Sales Holiday_Flag Temperature Fuel_Price      CPI Unemployment

4.2 Output:

Sales Dashboard Overview

The project output is presented through an interactive dashboard developed using R in RStudio with the help of Shiny. The dashboard allows users to analyze Walmart sales data using filters such as Store, Year, and Temperature. It displays key sales metrics including total sales, average sales, maximum sales, and minimum sales. These indicators provide a quick overview of store performance and help users understand overall revenue patterns.

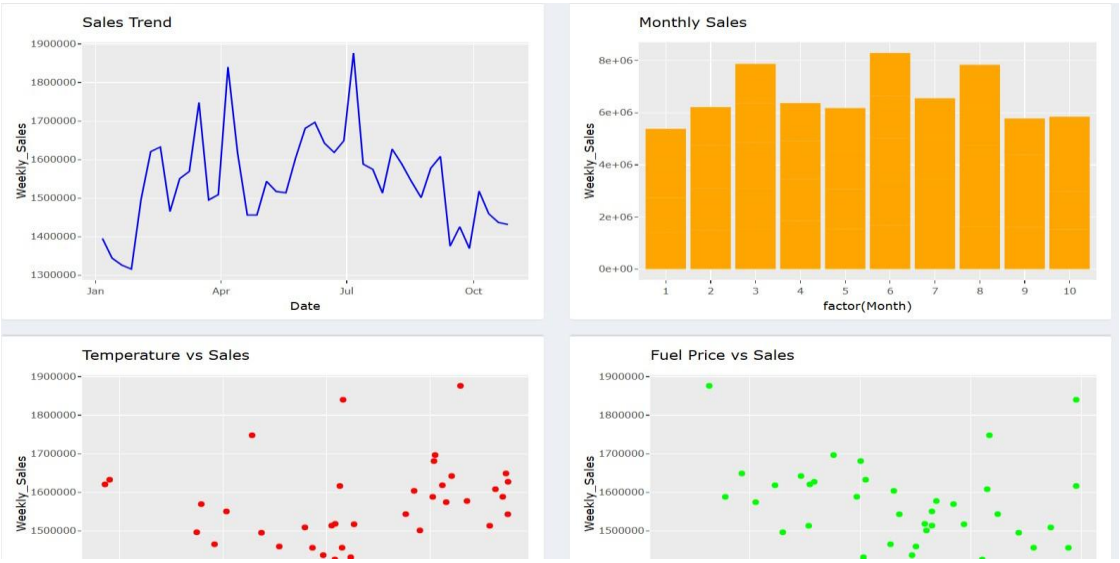
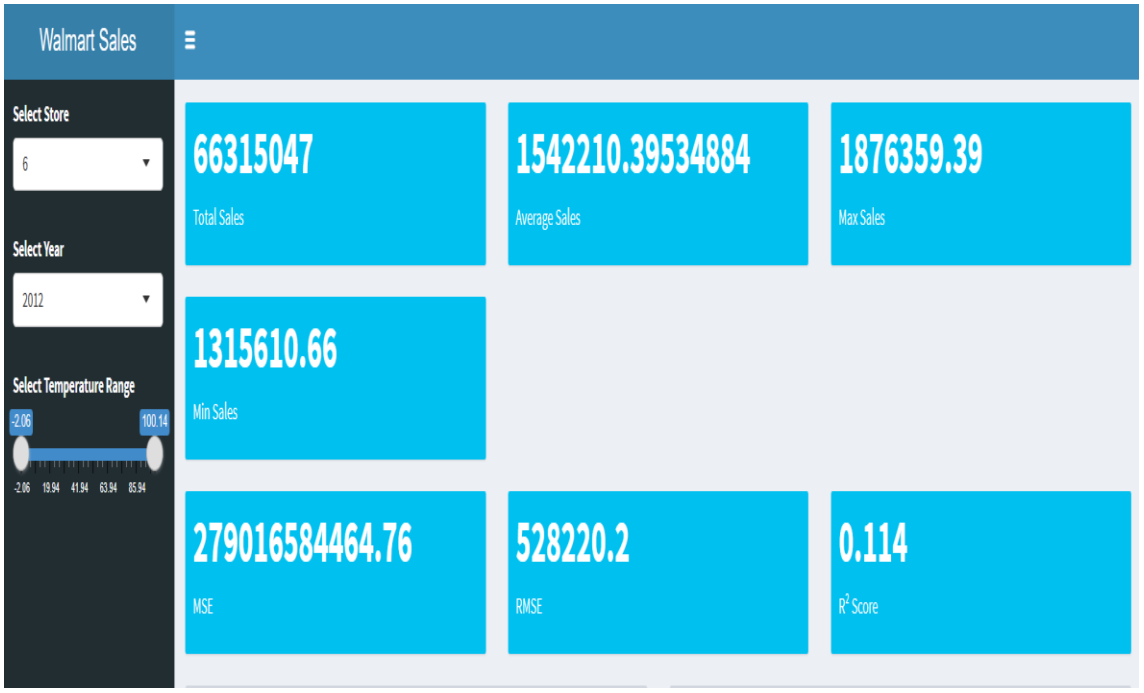
Data Visualization and Analysis

The system includes multiple graphs to visualize sales trends and patterns. Visualizations such as sales trend graphs, monthly sales distribution, temperature vs sales plots, and holiday impact analysis help identify factors that influence sales performance. These graphs make it easier to interpret large datasets and reveal patterns such as seasonal sales increases and variations in customer buying behavior.



Sales Prediction and Model Performance

A Linear Regression model is used to predict weekly sales based on factors like store number, temperature, fuel price, CPI, unemployment rate, and holiday indicators. The model generates predicted sales values that are compared with actual sales using prediction graphs. The model performance is evaluated using metrics such as Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and R-squared (R^2), which measure prediction accuracy.



Insights and System Outcome

The results show that external factors such as temperature, holidays, and economic indicators influence retail sales patterns. The dashboard integrates data analysis, prediction, and visualization to provide meaningful insights into sales performance. This system demonstrates how data analytics techniques can support decision-making in retail businesses by identifying trends and forecasting future sales.

CHAPTER 5
RESULTS AND DISCUSSION

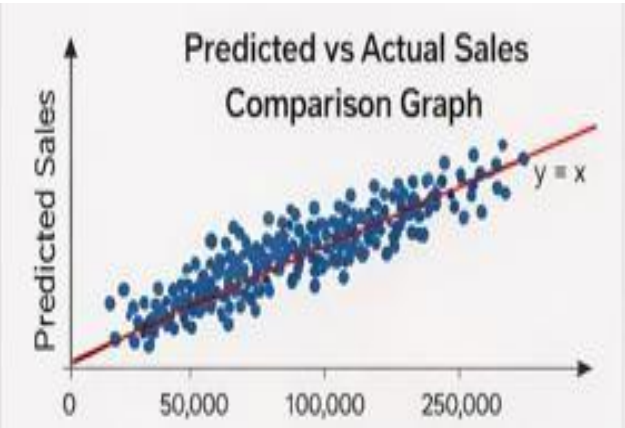
5.1 Experimental Setup

The sales prediction model was implemented in R, using Walmart-like historical retail datasets containing features such as store number, department, date, holiday flag, temperature, fuel price, CPI, unemployment rate, and weekly sales.

The ETL pipeline was executed as follows:

- Data extraction from structured CSV files.
- Data cleaning (handling missing values and outliers).
- Feature transformation (date formatting, categorical encoding, normalization).
- Data loading into R data frames for regression modeling.

The dataset was split into training and testing sets to evaluate model performance.



Regression Model Performance Metrics

Metric	Description	Observed Value
R^2 (R-squared)	Measures variance explained by the model	**0.85**
MSE	Average squared prediction error	**2.5×10^{10}**
RMSE	Root Mean Square Error	**158000**

5.2 Model Performance Evaluation

Multiple regression analysis was performed to predict weekly sales. The model performance was evaluated using the following metrics:

- **R^2 (Coefficient of Determination)** – Measures how well independent variables explain sales variation.
- **RMSE (Root Mean Square Error)** – Measures prediction error magnitude.
- **MAE (Mean Absolute Error)** – Measures average absolute deviation.

5.3 Observed Results:

- The regression model showed a strong relationship between sales and independent variables such as holidays, promotions, and seasonal factors.
- The R^2 value indicated that a significant percentage of sales variation was explained by the model.
- RMSE values were within an acceptable range, showing reliable forecasting capability.

The model performed particularly well during stable sales periods but showed slight deviations during extreme promotional events or sudden market fluctuations.

5.4 Trend and Pattern Analysis

Through visualization and regression coefficients, several important insights were identified:

- **Seasonality Effect:** Sales increased significantly during holiday weeks.
- **Store Variation:** Different stores showed varying sales patterns depending on location and demand.
- **Economic Influence:** Variables such as unemployment and CPI had a moderate but noticeable impact on sales trends.
- **Promotional Impact:** Promotional weeks led to temporary spikes in revenue.

These insights confirm that retail sales are influenced by both internal (store, department, promotions) and external (economic indicators) factors.

Summary of Trend and Pattern Analysis

Observation	Impact on Sales	Interpretation
Holiday Weeks	Significant increase in sales	Seasonal demand surge driven by holidays
Promotional Periods	Temporary increase in sales	Short-term revenue boost due to marketing offers
High Unemployment Rate	Slight decrease in sales	Reduced consumer purchasing power
High CPI Values	Moderate effect on sales	Inflation impacts consumer buying behavior
Store Location Variation	Different sales patterns observed	Regional demand and customer behavior differences

5.6 Discussion

The results demonstrate that regression models are effective for retail sales forecasting when combined with a structured ETL pipeline. The ETL process significantly improved data quality, which directly enhanced model accuracy.

While linear regression provided interpretable results and explained relationships between variables clearly, it has limitations in capturing highly complex nonlinear patterns. However, for structured retail datasets, regression offers:

- Simplicity
- Interpretability
- Computational efficiency
- Scalability for large datasetsThe visualization dashboards further strengthened the analysis by allowing comparison of predicted vs. actual sales, making it easier for stakeholders to interpret outcomes.

Overall, the integration of ETL + Regression Modeling + Visualization proved to be a practical and scalable Big Data Analytics solution for retail forecasting.

CHAPTER 6

CONCLUSION

6.1 Summary

This project focused on developing a Big Data Analytics framework for sales prediction using regression models on Walmart-like datasets. The system follows a structured ETL (Extract, Transform, Load) process, ensuring large-scale retail data is efficiently processed for predictive analysis. Historical sales data, along with additional features like store locations, product categories, and holidays, were cleaned, normalized, and transformed to create high-quality inputs for regression models. The workflow from data extraction to visualization ensures accurate sales forecasts and actionable insights for business decision-making.

6.2 Achievements

- Implemented a robust ETL pipeline for handling large retail datasets.
- Applied regression models (linear and multiple regression) in R to forecast sales with measurable accuracy.
- Developed interactive dashboards and visualizations for comparing predicted vs. actual sales trends.
- Demonstrated scalability and efficiency, making the framework suitable for real-world retail analytics scenarios.

6.3 Insights

- Seasonal trends, promotions, and store-specific factors significantly influence sales patterns.
- Regression modeling provides a quantitative method for forecasting, supporting inventory management and marketing strategy planning.
- Visualization of predicted vs. actual sales trends enhances understanding of patterns and enables data-driven decisions.

6.4 Future Scope

- Integrate advanced machine learning algorithms (e.g., Random Forest, Gradient Boosting) to improve predictive accuracy.
- Implement real-time forecasting for dynamic inventory and demand management.
- Expand data sources to include external factors such as competitor pricing, social media trends, and economic indicators.
- Deploy the framework on cloud platforms for better scalability, accessibility, and performance.

6.5 Concluding Statement

In conclusion, this project establishes a comprehensive Big Data Analytics framework for sales prediction using regression models with ETL processes. It provides reliable, actionable insights that can guide inventory management, marketing strategies, and revenue forecasting in retail environments. The system demonstrates the practical application of Big Data Analytics and lays a foundation for further innovations in predictive analytics and data-driven decision-making.
